

## **IN THE CLAIMS**

For the convenience of the Examiner, all pending claims of the Application are reproduced below.

1. (Currently Amended) A method for using a binary state machine for processing a data stream in an intrusion detection system, the method comprising:
  - maintaining a state table, the state table indexed such that inputs comprising a current state and a current character yield an output of a new state, the new state related to an indication of an attack on a computer network;
  - maintaining the current state;
  - receiving an input stream comprising, at a state machine of an intrusion detection device, an input stream destined for a first network device to be protected by the intrusion detection device, the input stream received at the state machine prior to reaching the first network device and comprising a first plurality of characters, a second plurality of characters, and at least one variable character between the first plurality and the second plurality of characters, wherein the first plurality and the second plurality of characters together constitute a REGEX signature a plurality of characters, wherein the first network device is operable to execute a program;
  - processing the first plurality of characters using the state table;
  - after processing the first plurality of characters, for each one of the at least one variable character:
    - selecting the variable character as the current character;
    - generating a state for the current character that is independent of the current character;
    - after generating the state, selecting a first character of the second plurality of characters input stream as the current character; and
    - after selecting the first character, comparing the current character and the current state to the state table to generate a new state.
2. (Original) The method of Claim 1, further comprising initializing the current state to an initial state.

3. (Currently Amended) The method of Claim 1, further comprising:  
    setting the current state equal to the new state;  
    selecting a next character of the second plurality of characters as the current character, the next character appearing subsequent to the first character ~~in the input stream~~;  
    and  
    repeating the comparing step.
4. (Original) The method of Claim 1, further comprising recognizing the new state as indicative of an attack upon the computer network.
5. (Original) The method of Claim 5, further comprising sounding an alarm.
6. (Original) The method of Claim 1, further comprising generating the state table from a REGEX command.
7. (Currently Amended) A system for use as a binary state machine for processing a data stream in an intrusion detection system, the system comprising:  
    a state table indexed such that inputs comprising a current state and a current character yield an output of a new state, the new state related to an attack on a computer network; and  
    a state machine communicatively coupled to the state table, the state machine operable to:  
        maintain the current state;  
        receive an input stream, the input stream comprising a first plurality of characters, a second plurality of characters, and at least one variable character between the first plurality and the second plurality of characters, wherein the first plurality and the second plurality of characters together constitute a REGEX signature destined for a first network device to be protected by the intrusion detection system, the input stream received prior to reaching the first network device and comprising a plurality of characters, wherein the first network device is operable to execute a program  
        process the first plurality of characters using the state table;  
        after processing the first plurality of characters, for each one of the at least one variable character:

select the variable character as the current character;  
generate a state for the current character that is independent of  
the current character;  
after generating the state, select a first character of the second plurality  
of characters ~~input stream~~ as the current character; and  
after selecting the first character, compare the current character and the  
current state to the state table to generate a new state.

8. (Original) The system of Claim 7 further comprising a computer readable medium, wherein the state table is stored upon the computer readable medium.

9. (Original) The system of Claim 8, wherein the state machine comprises software code stored upon the computer readable medium, the software code further operable to be executed by a computer processor.

10. (Original) The system of Claim 7, wherein the state machine is further operable to initialize the current state to an initial state.

11. (Currently Amended) The system of Claim 7, wherein the state machine is further operable to:

set the current state equal to the new state;  
select a next character of the second plurality of characters as the current character, the next character appearing subsequent to the first character in the ~~input stream~~;  
and  
repeat the comparing step.

12. (Original) The system of Claim 7, wherein the state machine is further operable to recognizing the new state as indicative of an attack upon the computer network.

13. (Currently Amended) A system for use as an intrusion detection system, the system comprising:  
a computer readable medium;

a network interface for receiving an input stream comprising a first plurality of characters, a second plurality of characters, and at least one variable character between the first plurality and the second plurality of characters, wherein the first plurality and the second plurality of characters together constitute a REGEX signature destined for a first network device to be protected by the intrusion detection system, the network interface operable to receive the input stream before the input stream reaches the first network device, the input stream comprising a plurality of characters transmitted by a second network device, wherein the first network device is operable to execute a program;

a processor communicatively coupled to the computer readable medium and the network interface;

a state table stored upon the computer readable medium, the state table indexed such that inputs comprising a current state and a current character yield an output of a new state, the new state related to an attack on a computer network; and

a state machine comprising instructions stored upon the computer readable medium and executable by the processor, the state machine communicatively coupled to the state table, the state machine operable to:

maintain the current state;

process the first plurality of characters using the state table;

after processing the first plurality of characters, for each one of the at least one variable character:

select the variable character as the current character;

generate a state for the current character that is independent of the current character;

after generating the state, select a first character of the second plurality of characters input stream as the current character; and

after selecting the first character, compare the current character and the current state to the state table to generate a new state.

14. (Currently Amended) A logic for using a binary state machine for processing a data stream in an intrusion detection system, the logic embodied in a computer-readable medium and operable to:

maintain a state table, the state table indexed such that inputs comprising a current state and a current character yield an output of a new state, the new state related to an indication of an attack on a computer network;

maintain the current state;

receive an input stream comprising a first plurality of characters, a second plurality of characters, and at least one variable character between the first plurality and the second plurality of characters, wherein the first plurality and the second plurality of characters together constitute a REGEX signature ~~an input stream destined for a first network device to be protected by the intrusion detection system, the input stream received at the logic prior to reaching the first network device and comprising a plurality of characters, wherein the first network device is operable to make a decision according to a program~~

process the first plurality of characters using the state table;

after processing the first plurality of characters, for each one of the at least one variable character:

select the variable character as the current character;

generate a state for the current character that is independent of the current character;

after generating the state, select a first character of the second plurality of characters ~~input stream~~ as the current character; and

after selecting the first character, compare the current character and the current state to the state table to generate a new state.

15. (Previously Presented) The logic of Claim 14, further operable to initialize the current state to an initial state.

16. (Currently Amended) The logic of Claim 14, further operable to:  
set the current state equal to the new state;  
select a next character of the second plurality of characters as the current character, the next character appearing subsequent to the first character in the ~~input stream~~;  
and  
repeat the comparing step.

17. (Previously Presented) The logic of Claim 14, further operable to recognize the new state as indicative of an attack upon the computer network.

18. (Canceled).

19. (Previously Presented) The logic of Claim 14, further operable to generate the state table from a REGEX command.

20. (Currently Amended) An intrusion detection system, comprising:  
means for maintaining a state table, the state table indexed such that inputs comprising a current state and a current character yield an output of a new state, the new state related to an indication of an attack on a computer network;  
means for maintaining the current state;  
means for receiving an input stream comprising a first plurality of characters, a second plurality of characters, and at least one variable character between the first plurality and the second plurality of characters, wherein the first plurality and the second plurality of characters together constitute a REGEX signature destined for a first network device to be protected by the intrusion detection system, the input stream received at the means for receiving the input stream prior to reaching the first network device and comprising a plurality of characters, wherein the first network device is operable to execute a program;  
means for processing the first plurality of characters using the state table;  
means for selecting, after the first plurality of characters has been processed, each one of the at least one variable character as the current character and generating, for each selected variable character, a state for the current character that is independent of the current character;  
means for selecting a first character of the second plurality of characters ~~input stream~~ as the current character; and  
means for comparing the current character and the current state to the state table to generate a new state; and  
means for transmitting the copy of the input stream to the first network device if an attack on the computer network is not detected.

21. (Currently Amended) The method of Claim 1, and further comprising:  
setting the current state equal to the new state;

selecting a next character of the second plurality of characters as the current  
character, the next character appearing subsequent to the first character ~~in the input stream~~;

repeating the comparing step; and

wherein each character in the input stream is selected only once ~~the first character and  
the next character are each selected and compared only once.~~
